

ABSTRACT

**Door device for pressurised container and
container containing such a device**

A door device for a container includes at least one casing portion with an opening provided in that portion. The device comprises two hollow rectilinear profiles parallel to each other, fixed or formed on the external face of the casing on both sides of the opening and each containing a longitudinal opening in the form of a slot, and at least one element in the form of a plate having at rest a curvature resembling that of the casing portion containing the opening and comprising two opposite parallel edges each provided with a profiled longitudinal thickening, whose section causes retention in one of the hollow profiles and allows sliding therein. The hollow profiles thus form positive connection members and slide rails for the element(s) in the form of a plate(s) and guiding it (them) between a closed position of the opening and a disengaged or released position thereof.
